Abstract—Neuromorphic photonic processors promise orders of magnitude improvements in both speed and energy efficiency over purely digital electronic approaches. We will provide an overview of neuromorphic photonic systems and their application to machine learning and specifically deep learning inference with a hybrid digital electronics and analog photonics architecture based on silicon photonics. We will discuss scalability in the context of designing a full-scale neuromorphic photonic processing system, considering aspects such as signal integrity, noise, and hardware fabrication platforms.

Keywords—Silicon photonics, neuromorphic computing, machine learning, optical neural networks, optical computing.

There has been a substantial increase in the use of many-core parallel processing systems for a variety of tasks in high performance computing (HPC). Artificial intelligence (AI), in particular, is growing at an alarming pace: deep learning models have been doubling in size every 3.5 months, far outpacing Moore's law [1]. These systems have much greater communication overheads than classical von Neumann architectures such as CPUs, resulting in a dramatic increase of both the area and energy consumption of metal interconnects (see, for example, Ref. [2]). They are also bottlenecked computationally by the ability to perform matrix multiplications efficiently, which represent the most common operations in HPC. The most computationally expensive task in current AI models is the implementation of neural networks. Current deep learning models require dense, low-precision matrix computations. Digital instantiations of matrix (or tensor) units typically suffer from high communication overheads, expensive digital operations, and high latencies. On the other hand, photonic linear operations—such as passive fourier transforms [3] or matrix operations [4]—exhibit stark advantages in bandwidth density, latency, and energy.

Photonic technology has traditionally been used for long distance communication. However, modern bandwidth requirements and the standardization of silicon photonic integrated circuits (PICs) has led to the proliferation of shorter distance photonic links. For example, silicon photonic transceivers are now a pervasive component in datacenters. There has been growing interest in using silicon photonics as

an enabling platform for unconventional computing [5], [7-11]. This could result in a new class of ultrafast information processors for neuromorphic information and signal processing, machine learning, and HPC. Neuromorphic photonics [12] can enable new class of applications where low latency, high bandwidth, and low switching energies are paramount. These applications could include nonlinear programming (e.g. solving optimization problems and partial differential equations), scientific (e.g. protein folding simulations) and high-performance computing (e.g. vector-matrix multiplications), machine learning acceleration (e.g. deep learning inference, and ultrafast and online learning), and intelligent signal processing (e.g. wideband RF signals, fiber transmission equalization, spectral mining).

In this talk, we will provide an overview of current neuromorphic silicon photonics architectures including coherent approaches based on Mach-Zehnder interferometers [7], [11] and incoherent (multiwavelength) optoelectronic approaches based on microring resonators [5], [9], [10]. We also describe several real-world applications for control and deep learning inference. Lastly, we will discuss scalability in the context of designing a full-scale neuromorphic photonic processing system, considering aspects such as signal integrity, noise, and hardware fabrication platforms.
